Chapter 1

Introduction

1.1 Revision History

Version	Date	Author(s)	Summary
1.0	21/01/16	Valerio Castelli & Fabrizio Casati	Initial release

1.2 Purpose and Scope

This document represents the Integration Testing Plan Document for my-TaxiService.

Integration testing is a key activity to guarantee that all the different subsystems composing myTaxiService interoperate consistently with the requirements they are supposed to fulfill and without exhibiting unexpected behaviors. The purpose of this document is to outline, in a clear and comprehensive way, the main aspects concerning the organization of the integration testing activity for all the components that make up the system. In the following sections we're going to provide:

- A list of the subsystems and their subcomponents involved in the integration activity that will have to be tested
- The criteria that must be met by the project status before integration testing of the outlined elements may begin
- A description of the integration testing approach and the rationale behind it
- The sequence in which components and subsystems will be integrated
- A description of the planned testing activities for each integration step, including their input data and the expected output

- Some performance measures that should be performed on the components to check they are fulfilling the requirements
- A list of all the tools that will have to be employed during the testing activities, together with a description of the operational environment in which the tests will be executed

1.3 Definitions, Acronyms, Abbreviations

1.3.1 Definitions

- Subcomponent: each of the low level components realizing the functionalities of a subsystem.
- Subsystem: a high-level functional unit of the system.

1.3.2 Acronyms

- SDD: Software Design Description.
- DD: Design Document. Used as a synonym of SDD.
- DBMS: Database Management System.
- API: Application Programming Interface.
- RASD: Requirement Analysis and Specification Document.
- SRS: Software Requirements Specifications. Synonym of RASD.
- ETA: Estimated Time of Arrival.
- UI: User Interface.
- GPS: Global Positioning System.
- SDK: Software Development Kit.

1.3.3 Abbreviations

- Req. as for Requirement.
- WebApp as for Web Application.

1.4 Reference Documents

- The project description document: Assignments 1 and 2 (RASD and DD).pdf
- Assignment document: Assignment 4 integration test plan.pdf
- myTaxiService Requirement Analysis and Specification Document: RASD.pdf
- myTaxiService Design Document: DD.pdf
- The Integration Test Plan Example document: Integration Test Plan Example.pdf

Chapter 2

Integration Strategy

2.1 Entry Criteria

In order for the integration testing to be possible and to produce meaningful results, there are a number of conditions on the progress of the project that have to be met.

First of all, the **Requirements Analysis and Specification Document** and the **Design Document** must have been fully written. This is a required step in order to have a complete picture of the interactions between the different components of the system and their required functionalities.

Secondly, the integration process should start only when the estimated percentage of completion of every component with respect to its functionalities is:

- 100% for the Data Access Utilities component
- At least 90% for the Taxi Management System subsystem
- At least 70% for the System Administration and Account Management subsystems
- At least 50% for the client applications

It should be noted that these percentages refer to the status of the project at the beginning of the integration testing phase and they do not represent the minimum completion percentage necessary to consider a component for integration, which must be at least 90%. The choice of having different completion percentages for the different components has been made to reflect their order of integration and to take into account the required time to fully perform integration testing.

2.2 Elements to be Integrated

In the following paragraph we're going to provide a list of all the components that need to be integrated together.

As specified in myTaxiService's Design Document, the system is built upon the interactions of many high-level components, each one implementing a specific set of functionalities. For the sake of modularity, each subsystem is further obtained by the combination of several lower-level components. Because of this software architecture, the integration phase will involve the integration of components at two different levels of abstraction.

At the lowest level, we'll integrate together those components that depend strongly on one another to offer the higher level functionalities of myTaxiService. In our specific case, this involves the integration of the Reservation Management, Request Management, Location Management and Taxi Management subcomponents in order to obtain the Taxi Management System subsystem.

For what concerns the building of the **System Administration** and **Account Management** subsystems, the integration activity is actually quite limited; in fact, they simply represent a collection of functionalities belonging to the same area which however are not dependent on one another. As a result of this, their subcomponents don't really interact with each other, and the integration phase will be limited to the task of ensuring that the set of functionalities of each subcomponent is properly exposed by the subsystem. The components involved in this phase are:

- The API Permissions Management, Zone Division Management, Taxi Driver Management, Service Statistics and Plugin Management subcomponents in order to obtain the System Administration subsystem.
- The Passenger Registration, Login, Password Retrieval and Settings Management subcomponents in order to obtain the Account Management subsystem.

Some of these subcomponents also directly rely on higher level, atomic components: that is the case, for instance, of the dependency on the **Data Access Utilities** component. These dependencies will be taken care of in the integration process.

Finally, we will proceed with the integration of the higher level subsystems. In particular, the integration activity will involve:

- A number of commercial, already existing components used to achieve specific functionalities: these are the **DBMS**, **Mapping Service**, **Notification System** and **Remote Services Interface** components.
- Those components and subsystems specifically developed for myTaxiS-ervice, that are:

- On the server side: the Taxi Management System, System Administration, Account Management subsystems, together with the Data Access Utilities component.
- On the client side: the Administration Web Application,
 Passenger Web Application,
 Passenger Mobile Application and Taxi Driver Mobile Application components.

2.3 Integration Testing Strategy

The approach we're going to use to perform integration testing is based on a mixture of the bottom-up and critical-module-first integration strategies.

Using the bottom-up approach, we will start integrating together those components that do not depend on other components to function, or that only depend on already developed components. This strategy brings a number of important advantages. First, it allows us to perform integration tests on "real" components that are almost fully developed and thus obtain more precise indications about how the system may react and fail in real world usage with respect to a top-down approach. Secondly, working bottom-up enables us to more closely follow the development process, which in our case is also proceeding using the bottom-up approach; by doing this we can start performing integration testing earlier in the development process as soon as the required components have been developed in order to maximize parallelism and efficiency.

Since subsystems are fairly independent from one another, the order in which they're integrated together to obtain the full system follows the critical-module-first approach. This strategy allows us to concentrate our testing efforts on the riskiest components first, that is those that represent the core functionalities of the whole system and whose malfunctioning could pose a very serious threat to the correct implementation of the entire my-TaxiService infrastructure. By proceeding this way, we are able to discover bugs earlier in the integration progress and take the necessary measures to correct them on time.

It should be noted that **Notification System**, **Remote Services Interface**, **Mapping Service** and **DBMS** are commercial components that have already been developed and can thus be immediately used in a bottom-up approach without any explicit dependency.

2.4 Sequence of Component/Function Integration

In this section we're going to describe the order of integration (and integration testing) of the various components and subsystems of myTaxiService. As a notation, an arrow going from component C1 to component C2 means

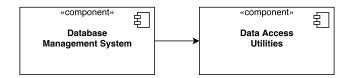

that C1 is necessary for C2 to function and so it must have already been implemented.

2.4.1 Software Integration Sequence

Following the already mentioned bottom-up approach, we now describe how the various subcomponents are integrated together to create higher level subsystems.

Data Access Utilities

The first two elements to be integrated are the **Data Access Utilities** and the **Database Management System** components. We start from here because every other component relies on **Data Access Utilities** to perform queries on the underlying data structure.

Taxi Management System

The second step in the integration process is to appropriately connect the subcomponents implementing the **Taxi Management System**. This choice comes from the critical-module-first approach, because taxi management is the single most important functionality of myTaxiService.

In the following diagrams, we are going to show exactly which components must be integrated together in order to implement this functionality using a bottom-up approach.

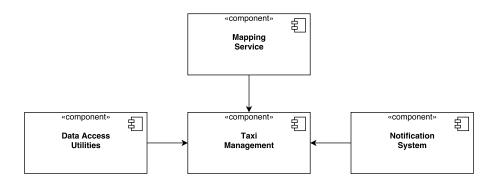

First, we proceed by integrating together the **Request Management** subcomponent with the **Data Access Utilities** and the **Notification System** components.

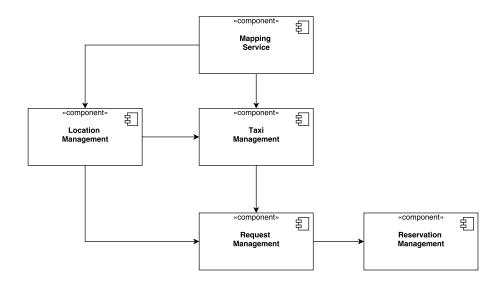

The same activity is performed between the Reservation Management subcomponent and the Data Access Utilities and the Notification System components.

Finally, we integrate together the **Taxi Management** component with the **Data Access Utilities**, the **Notification System** and the **Mapping Service** components.

At this point, the four sub-components of **Taxi Management System** are ready to be integrated together.

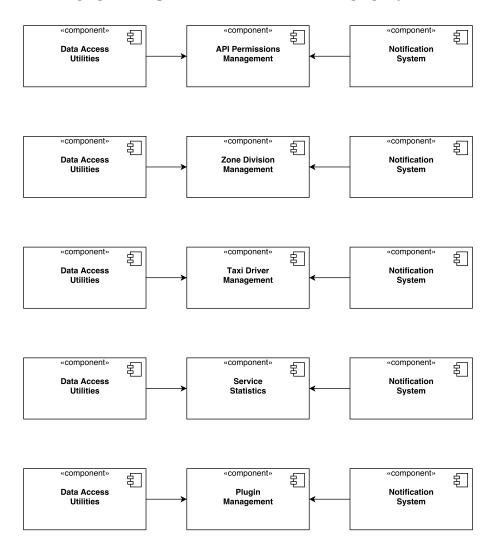

System Administration

The third step in the integration process is to appropriately connect the subcomponents implementing the **System Administration** subsystem. This choice comes from the critical-module-first approach, because system administration is the second most important functionality of myTaxiService. Once it has been integrated and tested, we can use this functionality to more easily populate the database for the following integration tests.

It should be noted that the subcomponents of **System Administration** are loosely coupled together as they cover different aspects of the system administration activity. Because of this, they can be integrated with the other components of the system independently from one another.

In the following diagrams, we are going to show exactly how these subcomponents interact with the other components using a bottom-up approach. The **System Administration** subsystem, which here is not explicitly represented, is simply a wrapper for the methods of these subcomponents that have to be exposed to the other parts of the system and performs additional preprocessing to ensure these methods are properly called.

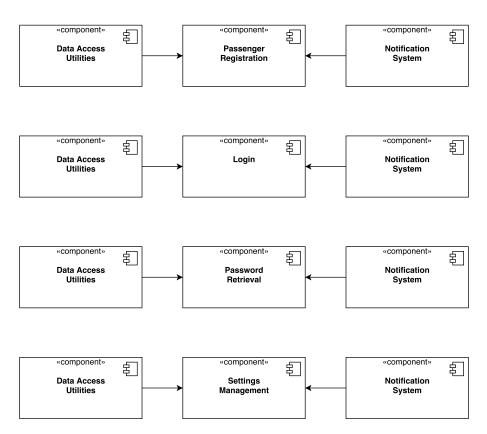

Account Management

The fourth step in the integration process is to appropriately connect the subcomponents implementing the **Account Management** subsystem. This choice is dictated by the bottom-up approach that we are following, because account management is the last functionality that can be implemented without depending on anything but already implemented components.

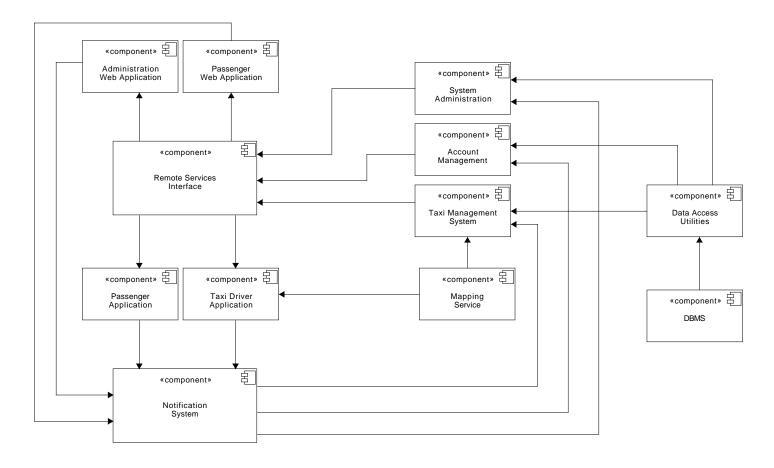

It should be noted that the subcomponents of **Account Management** are loosely coupled together as they cover different operations that can be performed on accounts. Because of this, they can be integrated with the other components of the system independently from one another.

In the following diagrams, we are going to show exactly how these subcomponents interact with the other components using a bottom-up approach. The **Account Management** subsystem, which here is not explicitly represented, is simply a wrapper for the methods of these subcomponents that have to be exposed to the other parts of the system and performs additional preprocessing to ensure these methods are properly called.

2.4.2 Subsystem Integration Sequence

In the following diagram we provide a general overview of how the various high-level subsystems are integrated together to create the full myTaxiService infrastructure.

Chapter 3

Individual Steps and Test Description

3.1 Taxi Management System

3.1.1 Request Management, Data Access Utilities

insertRequest(request)		
Input	Effect	
A null parameter	A NullArgumentException is raised.	
A request with an id already	An InvalidArgumentValueExcep-	
existent in the database	tion is raised.	
Formally valid arguments	An entry containing the request	
	data is inserted into the database.	
deleteRe	equest(request)	
Input	Effect	
A null parameter	A NullArgumentException is raised.	
A request with a inexistent id	An InvalidArgumentValueExcep-	
	tion is raised.	
Formally valid arguments	The entry containing the request	
	data is deleted from the database.	
getRequestList()		
Input	Effect	
Nothing	The list of all pending requests.	

insertReservation(reservation)		
	, , , , , , , , , , , , , , , , , , , ,	
Input	Effect	
A null parameter	A NullArgumentException is raised.	
A reservation with an id al-	An InvalidArgumentValueExcep-	
ready existent in the database	tion is raised.	
Formally valid arguments	An entry containing the reservation	
	data is inserted into the database.	
deleteReserv	vation(reservation)	
Input	Effect	
A null parameter	A NullArgumentException is raised.	
A reservation with a inexis-	An InvalidArgumentValueExcep-	
tent id	tion is raised.	
Formally valid arguments	The entry containing the reservation	
	data is deleted from the database.	
updateReservat	ionList(Reservation[])	
Input	Effect	
A null parameter	A NullArgumentException is raised.	
An empty array	An InvalidArgumentValueExcep-	
	tion is raised.	
An array containing some null	A NullArgumentException is raised.	
values		
An array of non-null, but in-	An InvalidArgumentValueExcep-	
existent reservations	tion is raised.	
An array of valid and existing	The corresponding entries in the	
reservations	database are updated to set the	
	reservation as completed.	
getRese	ervationList()	
Input	Effect	
Nothing	The list of all pending reservations.	

3.1.2 Reservation Management, Data Access Utilities

3.1.3 Taxi Management, Data Access Utilities Management

updateQueues(TaxiQueue[] tq)		
Input	Effect	
A null parameter	A NullArgumentException is raised.	
An empty array	An InvalidArgumentValueExcep-	
	tion is raised.	
An array containing some null	A NullArgumentException is raised.	
values		
An array of non-null queues,	An InvalidArgumentValueExcep-	
but containing null values	tion is raised.	
A non-empty array of valid	The content of the queues is up-	
queues	dated in the database.	
updateTaxiLoca	ation(taxiId, location)	
Input	Effect	
A null location	A NullArgumentException is raised.	
A set of valid parameters	The new location of the taxi is writ-	
	ten in the database.	
updateTaxiStatus(ta	xiId, TaxiStatusAvailable)	
Input	Effect	
A null parameter	A NullArgumentException is raised.	
A set of valid parameters	The taxi status is set to available in	
	the database.	

3.1.4 Taxi Management, Location Management

3.1.5 Reservation Management, Location Management

getZo	ne(location)
Input	Effect
A null parameter	A NullArgumentException is raised.
A location whose coordinates	An InvalidLocationException is
are invalid	raised.
A location outside the city	An InvalidLocationException is
	raised.
A location inside the city	The id of the zone to which the lo-
	cation belongs.
checkTaxiDriverLocation(currentLocation, meetingPoint)
Input	Effect
A null parameter	A NullArgumentException is raised.
A currentLocation whose co-	An InvalidLocationException is
ordinates are invalid	raised.
A meetingPoint whose coordi-	An InvalidLocationException is
nates are invalid	raised.
A currentLocation outside the	Returns false.
city	
A meetingPoint outside the	An InvalidLocationException is
city	raised.
Both currentLocation and	Returns false.
meetingPoint inside the city,	
but not within 50m from one	
another	
Both currentLocation and	Returns false.
meetingPoint inside the city,	
within 50m from one another	

${\bf 3.1.6}\quad {\bf Reservation\ Management,\ Request\ Management}$

requestTaxi(passengerId, passengerLocation, destination)		
Input	Effect	
A null parameter	A NullArgumentException is raised.	
A passengerId not correctly	An InvalidArgumentFormatExcep-	
formatted	tion is raised.	
A passengerLocation whose	An InvalidLocationException is	
coordinates are invalid	raised.	
A destination whose coordi-	An InvalidLocationException is	
nates are invalid	raised.	
A passengerLocation outside	A passengerId not correctly format-	
the city	ted	
A valid set of parameters	A new request is created and han-	
	dled; refer to the RASD for the spe-	
	cific outcomes of this operation.	

3.1.7 Request Management, Taxi Management

existsAvailableTa	axiDriver(request, zone)
Input	Effect
A null parameter	A NullArgumentException is raised.
An inexistent zone	An InvalidArgumentValueExcep-
	tion is raised.
A zone with invalid fields	An InvalidArgumentValueExcep-
	tion is raised.
A valid set of parameters	true if a taxi driver is available to
	serve the request, false otherwise
getETA(taxiDriv	ver, passengerLocation)
Input	Effect
A null parameter	A NullArgumentException is raised.
A passengerLocation whose	An InvalidLocationException is
coordinates are invalid	raised.
An inexistent taxi driver	An InvalidArgumentValueExcep-
	tion is raised.
A valid taxiDriver and passen-	Returns the estimated time of the
gerLocation	arrival of the taxi to the location.
taxiDriverDro	ppedRequest(taxiId)
Input	Effect
An invalid taxiId	An InvalidArgumentValueExcep-
	tion is raised.
A valid taxiId	If the taxi driver is allowed to drop
	the request (check RASD condi-
	tions), it will return true, notify the
	passenger that his request has been
	dropped and update the database
	accordingly; otherwise it will return
10	false.
	cation(taxiId, location)
Input	Effect
A null location	A NullArgumentException is raised.
A location whose coordinates	An InvalidLocationException is
are invalid	raised.
An invalid taxiId	An InvalidArgumentValueExcep-
:Td :1:d 14: :- :-	tion is raised.
taxiId is valid, location is in-	Location is set as the new position of
side city	the taxi, the taxi is moved into the
	new zone, its status is set as available and the modification is written
	in the database.
taxiId is valid, location is out-	Location is set as the new position of
side city	the taxi, the taxi is moved into the
F. Casati, V. Castelli	out etax, the tax is moved into the
•	outide-city and the modification is
	written in the database.

System Administration 3.2

3.2.1 Zone Management, Data Access Utilities

insertZones(Zone[] zones		
Input	Effect	_
A null parameter	A NullArgumentException is raised.	-
An empty array	An InvalidArgumentValueExcep-	-
	tion is raised.	
An array containing some null	A NullArgumentException is raised.	_
values

	raised.
A location inside the city	The id of the zone to which the lo-
	cation belongs.

Chapter 4

Performance analysis

While a full fledged performance analysis of the entire myTaxiService infrastructure will be executed only in the system integration phase, it is still useful to perform some preliminary measures on components whose performances can be tested in isolation.

In particular, it is appropriate to verify that the applications for all the target mobile platforms, regardless whether they're destined to taxi drivers or to passengers, have reasonable CPU and main memory usages.

As specified in the RASD, the performance requirements of the mobile applications are the followings:

- They must run correctly on smartphones with single core processors clocked at 800Mhz or more.
- They must use no more than 64 MB of RAM to execute.

Furthermore, even though no strict value is fixed at this point, the storage occupation should be reasonably small. Given the current trends in the size of the image assets needed to support high resolution devices, it is reasonable to expect a 30MB size cap; however, this number should be reconsidered during the development phase taking into account the improvements in the smartphone and tablet technology that may occur meanwhile.

These tests will be performed using the appropriate performance analysis tool provided with the SDK of each mobile platform.

Chapter 5

Tools and Test Equipment Required

5.1 Tools

In order to test the various components of myTaxiService more effectively, we are going to make usage of a number of automated testing tools.

For what concerns the business logic components running in the Java Enterprise Edition runtime environment, we are going to take advantage of two tools.

The first one is the **Arquillian integration testing framework**. This tool enables us to execute tests against a Java container in order to check that the interaction between a component and its surrounding execution environment is happening correctly (as far as the Java application server is involved). Specifically, we are going to use Arquillian to verify that the right components are injected when dependency injection is specified, that the connections with the database are properly managed and similar container-level tests

The second tool is the **JUnit framework**. Though this tool is primarily devoted to unit testing activities, it's still a valid instrument to verify that the interactions between components are producing the expected results. In particular, we are going to use it in order to verify that the correct objects are returned after a method invocation, that appropriate exceptions are raised when invalid parameters are passed to a method and other issues that may arise when components interact with each other.

Furthermore, as we have already mentioned briefly in the previous chapter of this document, we are going to use specific performance analysis tools to make sure that the applications for all the target mobile platforms, regardless whether they're destined to taxi drivers or to passengers, have reasonable CPU and main memory usages. Depending on the specific platform we are targeting, the tools we are going to use are:

- On Android: the Memory Profiler, Memory Monitor and Allocation Tracker tools to monitor main memory usage; the Traceview Walkthrough to monitor method execution time and the Battery Profiler to monitor energy consumption.
- On iOS: the full suite of performance analysis tools provided by the Xcode IDE. This includes Instruments as a general performance profiling tool, MallocDebug to find memory leaks, Activity Monitor and BigTop to monitor system statistics such as CPU, disk, network and memory usage.
- On Windows Phone: the Windows Phone Application Analysis toolkit, specifically the Windows Performance Analyzer tool.

Finally, it should be noted that despite the usage of automated testing tools, some of the planned testing activities will also require a significant amount of manual operations, especially to devise the appropriate set of testing data.

5.2 Test Equipment

All the integration testing activities have to be performed within a specific testing environment.

Since myTaxiService incorporates both a set of client components and a backend infrastructure, we must define the characteristics of the devices that have to be used in each of these two areas.

For what concerns the mobile client side of the testing environment, the following devices are required:

- At least one Android smartphone for each display size from 3" to 6" at steps of 1/2".
- At least one Android tablet for each display size from 7" to 12" at steps of 1/2".
- At least one iOS smartphone for each member of the iOS product family.
- At least one iOS tablet for each display size of the iOS product family.
- At least one Windows Phone smartphone for each display size from 3" to 6" at steps of 1/2".

These devices will be used to test both the native mobile applications and the mobile versions of the web applications. It should be noted that these are general guidelines to drive the selection of the testing devices in a way that covers the widest range of possible configurations. Some display sizes or resolutions may not be offered by all product families.

As a general note, we should consider the possibility of performing an analysis of the smartphone market to identify the most common display sizes and resolutions right before starting the integration testing phase, in order to better reflect the typical usage scenarios we will encounter in the real operating environment.

Regarding the desktop web applications, they will be tested using a set of normal desktop and notebook computers. There are no specific requirements on display resolution, operating system and processing power.

As for the backend testing, the business logic components should be deployed on a cloud infrastructure that closely mimics the one that will be used in the operating environment. Specifically, the testing cloud infrastructure needs to run the same operating system, the same Java Enterprise Application Server, the same Notification System and Remote Services Interface middleware (message brokers) and the same DBMS. As such, it is strongly required to use a scaled down version of the final operating cloud infrastructure chosen from the same service provider.

Depending on the actual implementation decisions, the specific software components may change. As a preliminary draft we assume to be using the **Red Hat OpenShift cloud infrastructure**, that is built upon the following software components:

- The Red Had Enterprise Linux distribution
- The Java Enterprise Edition runtime
- The GlassFish Java Application Server
- The GlassFish Message Broker
- The Apache Web Server as an HTTP load balancer
- The Oracle Database Management System.

Chapter 6

Required Program Stubs and Test Data

6.1 Program Stubs and Drivers

As we have mentioned in the Integration Testing Strategy section of this document, we are going to adopt a bottom-up approach to component integration and testing.

Because of this choice, we are going to need a number of drivers to actually perform the necessary method invocations on the components to be tested; this will be mainly accomplished in conjunction with the JUnit framework.

Here follows a list of all the drivers that will be developed as part of the integration testing phase, together with their specific role.

- Data Access Driver: this testing module will invoke the methods exposed by the Data Access Utilities component in order to test its interaction with the DBMS.
- Request Management Driver: this testing module will invoke the methods exposed by the Request Management subcomponent, including those with package-level visibility, in order to test its interaction with the Data Access Utilities, the Notification System, the Location Management and the Taxi Management components.
- Reservation Management Driver: this testing module will invoke the methods exposed by the Reservation Management subcomponent, including those with package-level visibility, in order to test its interaction with the Data Access Utilities, the Notification System and the Request Management components.
- Location Management Driver: this testing module will invoke the methods exposed by the Location Management subcomponent, in-

cluding those with package-level visibility, in order to test its interaction with the **Mapping Service** external component.

- Taxi Management Driver: this testing module will invoke the methods exposed by the Taxi Management subcomponent, including those with package-level visibility, in order to test its interaction with the Data Access Utilities, the Notification System, the Location Management and the Mapping Service components.
- API permissions Management Driver, Zone Divison Management Driver, Taxi Driver Management Driver, Service Statistics Driver, Plugin Management, Passenger Registration Driver, Login Driver, Password Retrieval Driver and Settings Management Driver: each testing module will invoke the methods exposed by its correspondent component to test its interaction with the Data Access Utilities and the Notification System components.
- Taxi Management Driver: this testing module will invoke the methods exposed by the Taxi Management subsystem to test its interactions with the Data Access Utilities, the Notification System and the Mapping Service components.
- Account Management Driver: this testing module will invoke the methods exposed by the Account Management subsystem to test its interactions with the Data Access Utilities and the Notification System components.
- System Administration Driver: this testing module will invoke the methods exposed by the Taxi Management subsystem to test its interactions with the Data Access Utilities and the Notification System components.

While the bottom-up approach in general doesn't require the usage of any stubs as the system is developed from the ground up, a full test of the core system isn't possible without introducing a few of them. In fact, there is a mutual dependency between the clients (which send requests) and the core system (which replies to them). Since we are developing and integrating the system from the core, we are going to introduce stubs to simulate the presence of clients until they are fully developed. In practice, the only purpose of these stubs is to write on a log that they have correctly received the messages.

6.2 Test Data

In order to be able to perform the battery of tests that we have specified, we are going to need:

- A list of both valid and invalid candidate taxi drivers to test the **Taxi Driver Management** component. The set should contain instances exhibiting the following problems:
 - Null object
 - Null fields
 - Taxi license not compliant with the legal format
 - Driving license not compliant with the legal format
- A list of both valid and invalid candidate passengers to test the **Passenger Registration** component. The set should contain instances exhibiting the following problems:
 - Null object
 - Null fields
 - Invalid mobile phone number
 - Invalid email address
- A list of both valid and invalid candidate city zones to test the Zone
 Division Management component. The set should contain instances
 exhibiting the following problems:
 - Null object
 - Null fields
 - Zones built as sequences of location vertices not producing a convex area, including the degenerate case in which the set has cardinality less than three
 - Zones built as sequences of vertices representing invalid or null locations
- A list of both valid and invalid candidate taxi requests to test the **Request Management** component. The set should contain instances exhibiting the following problems:
 - Null object
 - Null fields
 - Location is outside the city

- A list of both valid and invalid candidate taxi reservations to test the **Reservation Management** component. The set should contain instances exhibiting the following problems:
 - Null object
 - Null fields
 - Source location is outside the city
 - The time of the meeting does not respect the validity range

More specific information about the required test data can be found by analyzing the inputs of all the test cases described in chapter 3.
